

```
#include <stdlib.h>
#include <string.h>
#include <ctype.h>

#define MAXPAROLA 30
#define MAXRIGA 80

int main(int argc, char *argv[])
{
    int freq[MAXPAROLA]; /* vettore di contatori
                           delle frequenze delle lunghezze delle parole */
    char riga[MAXRIGA];
    int i, inizio, lunghezza;
    FILE * f;

    for(i=0; i<MAXPAROLA; i++)
        freq[i]=0;

    if(argc != 2)
    {
        fprintf(stderr, "ERRORE, serve un parametro con il nome del file\n");
        exit(1);
    }
    f = fopen(argv[1], "rt");
    if(f==NULL)
    {
        fprintf(stderr, "ERRORE, impossibile aprire il file %s\n", argv[1]);
        exit(1);
    }

    while( fgets( riga, MAXRIGA, f ) != NULL )
```

Deadlock

Deadlock prevention techniques

Stefano Quer and Pietro Laface

Politecnico di Torino

Prevention techniques

- ❖ Try to control how to apply the resources to prevent the occurrence of at least one of the necessary conditions
 - Mutual exclusion
 - Hold and wait
 - No preemption
 - Circular wait

Mutual exclusion

- ❖ A deadlock occurs because of "mutual exclusion" when a process is indefinitely waiting a resource
 - Thus, deadlock could be avoided if
 - 1. All resources were shareable (e.g., read-only)
 - 2. A process could not wait for a resource immediately non available
 - Strategy 1
 - Allow only shareable resources.
 - This strategy is generally considered very restrictive
 - Strategy 2
 - Inhibit a process to wait for a resource that is not immediately available.
 - This strategy is considered complex to be implemented

Hold and wait

A deadlock occurs because of a "hold and wait" condition, where a process request further resources while holding one or more resources.

So a hold and wait condition can be avoided by imposing that a process waits for a resource only when it does not hold others

Request All First (RAF)

A process must acquire all the necessary resources before starting its processing activities

- Poor resource usage
- Resources may be assigned a long time in advance of their usage

Release Before Request (RBR)

A process can request resources only when it has not previously acquired other resources

- Before each new request each process must release the resources already held
- Possibility of starvation
- Processes requiring many widely used resources may have to "start over" very often

No preemption

A deadlock occurs because no preemption is possible of a resource held by a process

In general is not easy to divert resources from a running process, but a similar effect can be obtained by means of the following strategies:

Allow preemption of resources held by the process itself

- If a process that holds some resources asks for another that cannot be immediately granted, it is forced to release all held resources (preemption).
- These resources are added to the list of resources that the process is waiting to acquire
- The process will be awakened only when it can regain its old resources, and the new one.

No preemption

A deadlock occurs because no preemption is possible of a resource held by a process

Allowing preemption of resources owned by another process as long as it is waiting

- If process P asks for a resource that is not immediately available, a search is performed for the process that currently holds it
- If a process Q is found, which is waiting for another resource, preempt from Q the resource and assign it to process A
- Otherwise, process P goes on the waiting state, so that the resources it hold can be preempted

Both strategies

- are suited for resources whose state can be easily saved and restored (CPU registers, main memory, etc.)
- are not suited for resources whose state cannot be recovered (files, printers, etc.)

Circular wait

A deadlock occurs because of a "circular wait" when a set of processes is waiting for a resource held by another set of processes

To avoid this condition one can impose a total ordering of all resource classes

Hierarchical Resource Usage (HRU)

- It imposes a total ordering relation between the various types of resources, associating to each of them an integer number. Example: HD = 1, DVD = 5, printers = 12
- Force each process to request resources with an increasing order of enumeration

In general, the HRU verification is applied by

- Programmer
- Operating system. The **witness** tool, available in FreeBSD UNIX version, checks the order of the lock acquired by processes

Circular wait

- ❖ Let F be the function that imposes a unique order among all classes of system resources R_i
 - Let a process have previously requested an instance of R_{old} resource, and now request a R_{new} instance
 - If $F(R_{new}) > F(R_{old})$
 - The resource is granted
 - If $F(R_{new}) \leq F(R_{old})$
 - The process must release all resources R_i such that $F(R_{new}) \leq F(R_i)$ before getting an instance of R_{new}
- ❖ It can be shown that this condition is sufficient to avoid the circular wait

Circular wait

- ❖ Let's suppose that there exists a set of processes that satisfy the HRU rules and are in circular wait

The order of requests requires that

$$F(R_k) < F(R_{k+1}), \quad \forall k = 0 \dots n-1.$$

This implies

$$F(R_0) < F(R_1) < \dots < F(R_n) < F(R_0) \\ F(R_0) < F(R_0),$$

which is absurd
